

# Coalescent theory

Population size determines coalescence rate

What if population size varies over time?  $N(t)$

[Like students adding/dropping mid-quarter in Coalescent theory]

$N(t)$  distorts time scale from the standard coalescent

- time compressed when  $N(t)$  is small
- time stretched when  $N(t)$  is large

The details:

$$P(T_i = t_i) = \frac{\binom{i}{2}}{2N_{t_i}} \prod_{j=2}^{t_i-1} \left(1 - \frac{\binom{i}{2}}{2N_j}\right)$$

$$\xrightarrow{\text{big } N} p(t_i) = \frac{\binom{i}{2}}{2N(t_i)} \exp\left(-\binom{i}{2} \int_0^t \frac{ds}{2N(s)}\right)$$

inhomogeneous Poisson process
